

# Statistical Testing 2 - Empirical Distributions

Daniel Lawson University of Bristol

Lecture 02.2.2 (v1.0.1)

# Resampling

- ▶ The main types of resampling tests include:
  - ▶ **jackknifing**, which is analysing subsets of data to estimate (variance of) parameter estimates
  - ▶ **bootstrapping**, which is resampling with replacement, to estimate (variance of) parameter estimates
  - ▶ **permutation**, which is resampling without replacement, to test a null hypothesis
  - ▶ **cross-validation**, which is analysing subsets of data to estimate out-of-sample prediction, for model performance
- ▶ Each of these methods can be applied to a wide variety of problems, and often requires thought to use appropriately.

# Permutations

All permutations of three colors (each column is a permutation):

► Figure from Wikipedia<sup>1</sup>. There are in general  $n!$  permutations.

---

<sup>1</sup>[https://upload.wikimedia.org/wikipedia/commons/4/4c/Permutations\\_RGB.svg](https://upload.wikimedia.org/wikipedia/commons/4/4c/Permutations_RGB.svg) / 23

# Generating permutations

```
> set.seed(1)
> n = 5
> x = seq(0,20,length=n)
> x
[1] 0 5 10 15 20
> x[sample.int(n)]
[1] 5 20 15 10 0
> x[sample.int(n)]
[1] 20 15 5 10 0
```

# Use of permutations in testing

- ▶ Consider the following general class of problem:
  - ▶  $H_0$ :  $y$  is independent of  $x$ .
  - ▶  $H_1$ :  $y$  is dependent on  $x$ .
- ▶  $x$  may be continuous, categorical, etc and  $y$  may depend on a number of other things.
- ▶ A **permutation test** will:
  - ▶ resample  $x, y$  pairs **under  $H_0$** ,
  - ▶ Construct a test statistic  $T$ ,
  - ▶ Test if  $T$  extreme in the real data, compared to the permutations?

# Why permutations

- ▶ The main advantage is that the test is asymptotically correct and distribution free. We only (!) have to assume **exchangability**.
- ▶ Exchangability of what?
  - ▶ what would be **equal if the null hypothesis is true**, and
  - ▶ would be **different if the alternative hypothesis is true**?
- ▶ It is essential to **maintain any true correlation structure** when performing the test, otherwise the test is not correct.
- ▶ For example, if the indices were originally correlated, permutation will fail.
  - ▶ as from e.g. a time-series.

## Some main types of test (1)

x1	x2	x3	y1	y2
4	12	-3	2	-24

- ▶ Permutation of **indices**:

x2	y1	x3	y2	x1
4	12	-3	2	-24

## Some main types of test (1)

x1	x2	x3	y1	y2
4	12	-3	2	-24

- ▶ Permutation of **indices**:

x2	y1	x3	y2	x1
4	12	-3	2	-24

- ▶ Permutation of **signs**, retaining magnitudes:

x1	x2	x3	y1	y2
4	-12	3	-2	24

## Some main types of test (2)

x1	x2	x3	y1	y2
4	12	-3	2	-24

- ▶ Permutation of **group** labels:

x1	y1	y2	x2	x3
4	12	-3	2	-24

## Some main types of test (2)

x1	x2	x3	y1	y2
4	12	-3	2	-24

- ▶ Permutation of **group** labels:

x1	y1	y2	x2	x3
4	12	-3	2	-24

- ▶ Permutation **within group** labels:

x1	x2	x3	y1	y2
12	-3	4	-24	2

# Monte-Carlo testing

- ▶ There are in general  $n!$  permutations. This is typically too many for  $n > 20$ .
- ▶ We instead choose  $N$  **random permutations** from all the possible ones.
- ▶ Monte-Carlo testing is an important subject in its own right.
- ▶ Its often possible to place guarantees on the  $p$ -value from very few samples.

# Monte-Carlo test

- ▶ To conduct a Monte-Carlo test, we construct  $N$  random datasets and add our real dataset.
- ▶ We then ask, is the **real dataset an outlier** with respect to the random datasets?
- ▶ Specifically, the p-value for a test  $T$  applied to  $X$  (where large values are considered strange) is:

$$\frac{\text{Rank}(T(X); T(\{x_i\}))}{N + 1}$$

- ▶ where Rank simply counts the number of cases as large or larger.

## Heuristics for how many permutations to use

- ▶ The **smallest possible p-value** with  $N$  permutations is  $1/(N + 1)$ . So 999 permutations gives a minimum of 0.001.
- ▶ The **variance** around a chosen threshold, say  $p = 0.05$ , is determined by the sampling distribution of the Binomial:

$$\text{sd}(p) = \text{sd}(\text{Bin}(N, p)) = \sqrt{\frac{p(1-p)}{n}}$$

- ▶  $p$  is of course the true unknown probability, not the observed one.
- ▶ But variance is an increasing function of  $p$  (for  $p < 0.5$ )
- ▶ A heuristic rule is: to be 95% confident that  $p \leq t$  we need the empirical p-value to be less than  $t - 1.96\text{sd}(p = t)$
- ▶ For  $N = 999$  and  $t = 0.05$ ,  $\text{sd}(p = t) = 0.0135$  and therefore  $p < 0.036$
- ▶ A similar calculation shows  $N = 999$  wouldn't be enough to be sure we were less than 0.005.
- ▶ This is conservative... only if the distribution is Normal...(!)  
**Plot the distribution of  $T$ !**

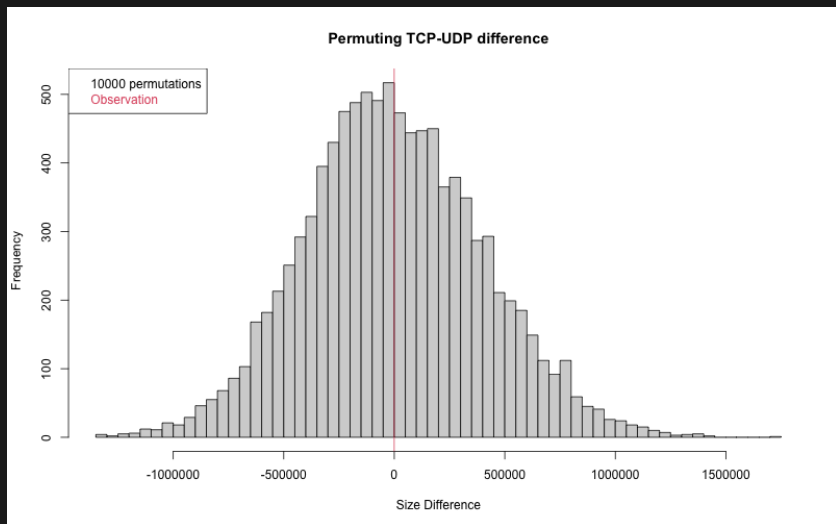

## Permutation example: TCP vs UDP size

```
tcpudp=c(tcpsize,udpsize)
n1=length(tcpsize)
n2=length(udpsize)
myteststatistic=function(x,n1,n2){
  mean(x[1:n1]) - mean(x[n1+(1:n2)])}
```

## Permutation example: TCP vs UDP size

```
tcpudp=c(tcpsize,udpsize)
n1=length(tcpsize)
n2=length(udpsize)
myteststatistic=function(x,n1,n2){
  mean(x[1:n1]) - mean(x[n1+(1:n2)])}
tobs=myteststatistic(tcpudp,n1,n2)
trep=apply(1:10000,function(i){
  xrep=sample(tcpudp)
  myteststatistic(xrep,n1,n2)
})
mean(tobs<=trep)
# 0
```

# Permutation example: TCP vs UDP size

## Permutation example: FTP vs UDP size

- ▶ T-test suggests that FTP and UDP are different sizes

```
muudp=mean(log(udpsize))  
t.test(log(ftpsize),mu=muudp)$p.value  
## 0.003375621
```

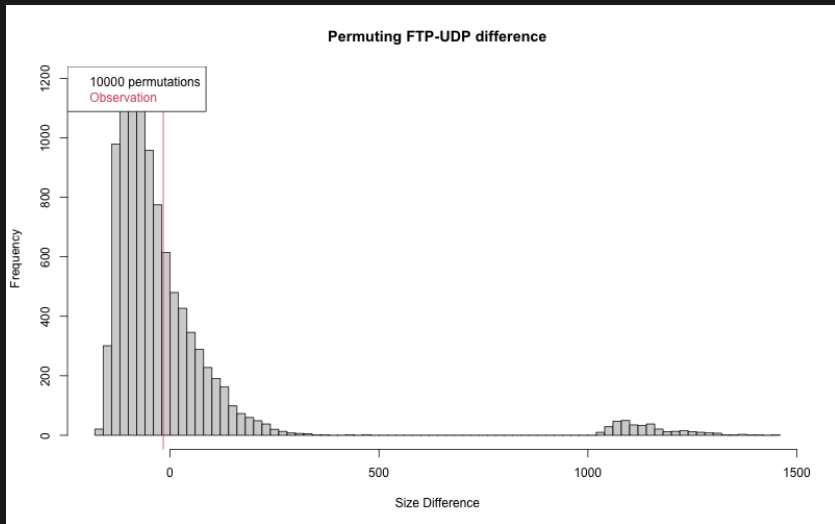

## Permutation example: FTP vs UDP size

```
ftpudp=c(ftpsize,udpsize)  
n1=length(ftpsize)  
n2=length(udpsize)
```

## Permutation example: FTP vs UDP size

```
ftpudp=c(ftpsize,udpsize)
n1=length(ftpsize)
n2=length(udpsize)
ftpudpobs=myteststatistic(ftpudp,n1,n2)
ftpudpprep=sapply(1:10000,function(i){
  xrep=sample(ftpudp)
  myteststatistic(xrep,n1,n2)
})
mean(ftpudpobs<=ftpudpprep)
## 0.3315
```

# Permutation example: FTP vs UDP size

# Permutation testing summary

- ▶ **Distributional assumptions** are often invalid (regular tests)
- ▶ **Exchangability assumptions** are often plausible (permutation tests)
- ▶ It is possible to get misleading inference if the assumptions of a test don't hold
- ▶ Permutation tests are really important for generating **plausible null hypotheses**, especially in cyber security

# Reflection

- ▶ When are sampling approaches to testing appropriate?
- ▶ What do they test?
- ▶ What are the main ways to implement them?
- ▶ What problems can resampling tests solve? Where are they still difficult to apply?
